Purpose of This Guideline

This guideline was developed by the New York State Department of Health AIDS Institute (NYSDOH AI) to inform clinicians who do not specialize in substance use treatment of the currently available and effective strategies for treating adult patients with opioid use disorder (OUD). With this guideline, the NYSDOH AI aims to:

- Assist clinicians in engaging with patients about OUD treatment goals, including overdose prevention.
- Provide up-to-date information about available OUD treatment options and their use.
- Provide clinical recommendations for the use of buprenorphine/naloxone to treat OUD in the nonspecialty setting.
- Increase the availability of nonspecialty treatment for adults with OUD.
- Promote a harm reduction approach to the treatment of all substance use disorders (SUDs), which involves practical strategies and ideas for reducing the negative consequences associated with substance use.

Goals of OUD Treatment

The United States is in the midst of an unprecedented opioid crisis, with dramatic increases observed in opioid use, OUD, and opioid-related overdose deaths [SAMHSA(a) 2021; Scholl, et al. 2018; Rudd, et al. 2016]. Data from the Centers for Disease Control and Prevention show an estimated 75,673 opioid-related overdose deaths in the 12 months ending in April 2021, an increase from the estimated 56,064 deaths in the prior year [CDC(b) 2021].

The rapid rise in opioid-related overdose deaths in recent years is driven by greatly increased exposure to illicitly manufactured fentanyl and fentanyl analogues. Since 2014, these high-potency synthetic opioids have been spreading in the illicit drug supply, often as adulterated or substituted heroin or pressed into counterfeit pills [Ciccarone 2021]. Illicitly manufactured fentanyl and fentanyl analogues currently account for more than 80% of opioid-related overdose deaths in the United States, increasing from a rate of 11.4 per 100,000 population in 2019 to 17.8 per 100,000 population in 2020 [CDC(a) 2021]. Additionally, other synthetic additives such as xylazine, a veterinary sedative, have been found with increasing frequency in the drug supply and have contributed to increases in morbidity and mortality [Gupta, et al. 2023; Alexander, et al. 2022; Korn, et al. 2021]. As of March 2023, fentanyl mixed with xylazine had been found in drugs confiscated in 48 states; the estimated number of drug-poisoning deaths in the United States involving xylazine increased from 260 in 2018 to 3,480 in 2021 [Gupta, et al. 2023].

Currently, 3 pharmacologic OUD treatment options are approved by the U.S. Food and Drug Administration: methadone, BUP, and extended-release (XR) naltrexone. Although pharmacologic treatment of OUD reduces overdose mortality by nearly 50%, only 1 out of 5 Americans with past-year OUD had received life-saving treatment in 2021, the most recent year for which data are available [Jones(b), et al. 2023; Krawczyk, et al. 2022; Laroche, et al. 2018; Sordo, et al. 2017]. Increased access and linkage to evidence-based OUD treatment is urgently needed given the opioid epidemic's continued toll on individuals, families, and communities. Implementing and scaling up effective OUD treatment across diverse settings is critical to curbing the opioid epidemic [CDC 2022].

Harm reduction as a treatment goal: A traditional goal of OUD treatment is abstinence or long-term cessation of opioid use. However, as fentanyl-fueled overdose deaths increase, harm reduction, including survival, has become an important goal. The mortality benefit of receiving medications for OUD remains strong even if a person intermittently uses opioids during treatment [Stone, et al. 2020]. In addition, abstinence may take time to achieve and may not be a realistic goal for all individuals. Other goals that can lead to substantial improvements in the health and lives of people with OUD and reduce harm include:

- Reducing the frequency and quantity of opioid use
- Reducing the risk and occurrence of overdose
- Staying engaged in care, which can facilitate prevention, diagnosis, and treatment of other medical and mental health conditions
- Reducing high-risk behaviors, such as injection drug use and sharing of injection equipment, and reducing related complications, such as infection
- Improving quality of life and other social indicators, such as employment and stable housing, and reducing the risk of incarceration

For more information, see NYSDOH AI guideline [Substance Use Harm Reduction in Medical Care](#).

→ KEY POINTS

- Harm reduction is a treatment goal.
- Provide overdose prevention counseling; prescribe, dispense, or offer resources for naloxone; and dispense or offer resources for fentanyl and xylazine test strips (if available) as part of OUD treatment evaluation.

Role of and Requirements for Clinicians

Primary care clinicians in New York State can play an essential role in identifying and treating OUD in their patients. Pharmacologic treatment for OUD in primary care settings reduces nonprescription opioid use and improves retention in treatment [Alford, et al. 2011; Altice, et al. 2011; Fiellin, et al. 2011; Lucas, et al. 2010; Cunningham, et al. 2008; Magura, et al. 2007; Mintzer, et al. 2007; Samet, et al. 2001]. One study examining BUP treatment for OUD in “real-world” primary care settings reported a 12-month retention rate of 74% among participants treated in a primary care clinic and 49% among those

referred to OUD treatment outside of the primary care clinic [Lucas, et al. 2010]. In addition, a study among individuals with HIV demonstrated that retention in primary care-based BUP treatment is associated with the initiation of antiretroviral therapy and improved viral load suppression [Altice, et al. 2011]. Similarly, a study among individuals with hepatitis C virus (HCV) reported that retention in primary care-based BUP treatment was associated with a higher likelihood of being evaluated and offered treatment for HCV infection [Norton, et al. 2017].

In light of the opioid crisis, all clinicians in New York State, including those who deliver primary care, should be informed about risk reduction and treatment options for OUD.

Federal requirements for clinicians: Federal policies regulate OUD treatment based on the assigned controlled substance classification under the U.S. Department of Justice Drug Enforcement Administration (DEA).

Buprenorphine is a schedule III-controlled substance that has been subject to evolving restrictions. Until 2022, physicians and advanced clinical specialists were required to apply for a separate DEA waiver (commonly known as the “DATA-waiver” or “X-waiver”) to prescribe any formulation of BUP for OUD. In January 2023, the [Consolidated Appropriations Act](#) (also known as the Omnibus bill) removed the federal requirement for a DEA waiver to prescribe BUP (see [DEA letter on DATA-Waiver Program](#)). With this provision, all clinicians who have a current DEA license to prescribe schedule III-controlled substances can now prescribe BUP for OUD without a patient limit. Effective June 2023, all clinicians who obtain or renew their DEA license will be required to complete 8 hours of training related to substance use (see [DEA letter on training requirement](#)). The effect of these policy changes will have to be assessed; however, the elimination of prescriber restrictions is anticipated to increase access to BUP treatment.

In contrast, methadone is a schedule II-controlled substance that can only be dispensed or administered for OUD treatment in specialty opioid treatment programs certified by the Substance Abuse and Mental Health Services Administration (SAMHSA) and single-state agencies for substance use services. Oral naltrexone and XR naltrexone are not scheduled substances and can be prescribed without clinician restrictions.

All 3 medications (BUP, methadone, and naltrexone) can be administered in any acute care setting, although restrictions apply for methadone (see [DEA: Narcotic Treatment Program Manual: A Guide to DEA Narcotic Treatment Program Regulations](#)).

Legal Protections for Individuals With OUD

The New York State Human Rights Law (NYSHRL) and the Americans With Disabilities Act (ADA) protect individuals with disabilities from discrimination. Under the NYSHRL and ADA, individuals taking prescribed medical treatment for OUD and those in recovery from OUD are considered disabled (see [The Americans with Disabilities Act and the Opioid Crisis: Combating Discrimination Against People in Treatment or Recovery](#)). The NYSHRL and the ADA *exclude* from protection individuals who are currently using illegal drugs.

Employers and housing providers are prohibited from discriminating against individuals with disabilities under the NYSHRL. Employers are prohibited from denying a job opportunity to a qualified individual, terminating an employee because of a disability, and making inquiries about an individual’s disability, which includes questions about prescribed medical care for OUD. Employers are required to provide reasonable accommodations to assist disabled people in performing their job functions. It is unlawful for housing providers, including skilled nursing facilities, to refuse to house or discriminate against a tenant because they are taking medical treatment for OUD or are in recovery from OUD.

Information about these protections and enforcement of the NYSHRL can be found at the [New York State Division of Human Rights](#).

Telehealth

Telehealth has the potential to reduce barriers to care for individuals with OUD. Historically, under the Ryan Haight Act of 2008, at least 1 in-person medical evaluation of a patient was required before prescribing controlled substances, including BUP. However, at the start of the COVID-19 Public Health Emergency (PHE), the DEA and SAMHSA issued exemptions to allow for BUP initiation through telehealth, including telephonic (audio-only) and video (audio-visual) visits, without first requiring an in-person visit [SAMHSA 2020]. Practitioners must still adhere to state-specific requirements for telehealth (see NYSDOH [Bureau of Narcotic Enforcement](#)). In New York State, both telephonic and video visits for initiating BUP were covered under Medicaid during the COVID-19 PHE [NYSDOH 2023; Chan, et al. 2022; Cunningham, et al. 2022]. In-person medical evaluation is still required to initiate methadone treatment. The long-term ability to initiate medication for OUD treatment via telehealth

remains unclear at this time; [PHE exemptions for telehealth have been extended through 2024](#) while new regulations are under review.

To date, observational studies have found that BUP treatment delivered through telehealth is associated with similar or improved treatment retention and reduced overdose risk compared with BUP treatment delivered through in-person visits [Jones(a), et al. 2023; Chan, et al. 2022; Cunningham, et al. 2022; Jones, et al. 2022]. Telehealth BUP treatment is feasible and effective for providing OUD treatment for patients who may have limited or no access to in-person clinical care, including patients who live in remote locations, are not stably housed, or are incarcerated [Williams, et al. 2023; Tofighi, et al. 2022; Belcher, et al. 2021; Weintraub, et al. 2021]. However, rigorous evaluation of telehealth-delivered BUP treatment is still needed to evaluate long-term treatment outcomes, address disparities in access, and implement best practices. Adults who are older, have low income, have limited English language proficiency, are members of ethnic or racial minorities, or who reside in areas with limited or no internet access may not be able to access telehealth services [NEJM Catalyst 2020]. Access to video visits may also be challenging among people who use drugs who do not have electronic devices, internet or mobile data access, or privacy.

In-person visits for new patients may help establish rapport and facilitate assessment of medical or mental health needs beyond OUD treatment and can be arranged according to an expected timeframe (e.g., within 2 to 4 weeks) without delaying OUD treatment initiation. To ensure treatment access equity, in-person visits should be prioritized for patients who prefer in-person visits or have clinical needs that may benefit from an in-person evaluation (e.g., recent overdose or other acute complications related to OUD, co-occurring SUDs that may increase overdose risk, unstable medical or mental health conditions, persistent concern for diversion). Treatment should not be withheld solely based on patient preference for telehealth or in-person visits.

Treatment Considerations

RECOMMENDATIONS

Overdose Prevention

- Clinicians should provide overdose prevention counseling (A3); prescribe, dispense, or offer resources for NLX (A2); and dispense or offer resources for fentanyl and xylazine test strips (if available) (A3) as part of OUD treatment evaluation [a].

Who to Treat

- Clinicians should offer pharmacologic treatment to adult patients with OUD (A1), including those who are not actively using opioids but are at risk of returning to use or overdose. (B3)
- Clinicians should *not* exclude patients from pharmacologic OUD treatment because of:
 - Previous OUD treatment failure, which is defined as the inability to adhere to medications for OUD or achieve treatment goals. (A3)
 - Lack of participation in structured psychosocial treatment, such as counseling, cognitive behavioral therapy, or contingency management [b]. (A1)
 - Co-occurring substance use or SUD. (A2)
- Before discharging a patient treated for an opioid-related overdose or complication, and as medically indicated, clinicians in an ED or other acute care setting should initiate or recommend pharmacologic OUD treatment. (A1)

Treatment Options

- Clinicians should obtain complete histories of patients' previous OUD treatment, including tolerance of and success with medication initiation, experience with long-term treatment, adherence challenges, adverse effects, treatment duration, and reasons for stopping treatment. (A2)
- BUP/NLX and methadone are the preferred treatments for OUD. Clinicians should inform patients with OUD about all available pharmacologic options (BUP, methadone, and XR naltrexone) and all formulations. (A3) See the guideline sections [Buprenorphine/Naloxone](#), [Methadone](#), and [Naltrexone](#).
- Because OUD is a chronic condition, clinicians should recommend long-term pharmacologic treatment rather than withdrawal management alone. (A1)

RECOMMENDATIONS

- In choosing the best option for OUD treatment, clinicians should engage patients in shared decision-making that accounts for the patient's opioid tolerance and preferences, available and accessible options, and comorbidities. (A3)

Abbreviations: BUP, buprenorphine; ED, emergency department; NLX, naloxone; OUD, opioid use disorder; SUD, substance use disorder; XR, extended-release.

Notes:

- a. For full recommendations on overdose prevention, see NYSDOH AI guideline [Substance Use Harm Reduction in Medical Care > Implementing Substance Use Harm Reduction](#).
- b. If a patient is court-ordered to participate in psychosocial therapy, the clinician's primary responsibility is to maintain the therapeutic alliance and partner with the patient to address legal mandates.

Overdose Prevention

An essential part of initiating and continuing OUD treatment is overdose prevention counseling. Counsel patients to:

- Assume all illicitly manufactured opioids will contain fentanyl or other high-potency synthetic opioids, and that stimulants and counterfeit pills may contain these agents.
- When possible, test drugs with fentanyl test strips, xylazine test strips, or other drug-checking equipment. Online sources include [MATTERS](#) (for New York State residents and programs, no charge), [DanceSafe](#), and [BTNX](#). Some [NYS Authorized Syringe Exchange Sites](#) may provide fentanyl test strips and other drug-checking systems.
- Try not to use drugs alone. Arrange for someone to check in; use phone- and web-based apps (e.g., [Never Use Alone Inc.](#) at 800-484-3731).
- When using any drug, start with a small amount.
- Carry NLX, learn how to use it, and encourage friends and contacts to do the same. The 4 mg NLX nasal spray formulation is available at pharmacies, at [NYSDOH-Registered Opioid Overdose Prevention Programs](#) (no charge), and online through [MATTERS](#) (for New York State programs and residents, no charge) and [NEXT Distro](#). NLX is covered by New York State Medicaid and the majority of private insurers.

In addition to overdose prevention counseling, clinicians should incorporate harm reduction into OUD treatment planning. For example, all patients who inject opioids or other drugs should be counseled on use of sterile needles and syringes. Licensed pharmacies, healthcare facilities, and clinicians can furnish hypodermic needles or syringes to individuals ≥ 18 years old without a patient-specific prescription; drug equipment is also available at [NYS Authorized Syringe Exchange Sites](#).

Who to Treat

SUDs, including OUD, have become widely recognized as chronic conditions [McLellan, et al. 2014]. OUD is associated with significant and persistent changes in brain structure and function. Naturally occurring endogenous opioids in the brain act on opioid receptors to produce effects on cognition, emotion, pain, sleep, and other domains [Maldonado 2010]. With repeated exposure to external (exogenous) opioids, the brain's opioid system may no longer be able to self-regulate [Volkow, et al. 2019; Volkow and Koob 2015]. When this occurs, tolerance to opioids develops, the brain produces lower levels of endogenous opioids, and a larger dose of exogenous opioids is required to obtain the same effects [Volkow, et al. 2016; Williams, et al. 2013]. In addition, physical withdrawal symptoms can develop within hours of discontinuing or reducing opioid use [Kampman and Jarvis 2015].

Clinicians should offer pharmacologic treatment to adult patients diagnosed with OUD, including patients who are not actively using opioids (see Box 1, below). Pharmacologic treatment is essential in stabilizing and restoring chronic changes in brain structure and function. By alleviating opioid cravings and withdrawal symptoms, pharmacologic treatment can also help individuals focus on improving behavioral components of OUD.

Pharmacologic treatment should be offered to individuals diagnosed with OUD who are not actively using opioids but who are at risk of resuming opioid use. Two important risk factors for return to use and overdose among individuals with OUD are a history of overdose and leaving a controlled setting, such as prison, jail, hospital, or other treatment facilities [Olfson, et al. 2018; Binswanger, et al. 2013]. Medical care, including hepatitis C virus and HIV screening, prevention, and treatment, as indicated, should be offered to individuals with OUD regardless of whether they are engaged in OUD treatment.

Box 1: DSM-5 Diagnostic Criteria for Opioid Use Disorder [a]

The DSM-5 describes OUD as a pattern of opioid use that leads to problems or distress, with at least 2 of the criteria below occurring within 12 months. Severity of the OUD is determined by the number of criteria met: mild (2 to 3 criteria); moderate (4 to 5 criteria); and severe (≥ 6 criteria).

1. Taking larger amounts or taking drugs over a longer period than intended
2. Persistent desire or unsuccessful efforts to cut down or control opioid use
3. Spending a great deal of time obtaining or using the opioid or recovering from its effects
4. Craving, or a strong desire or urge to use opioids
5. Problems fulfilling obligations at work, school, or home
6. Continued opioid use despite having recurring social or interpersonal problems
7. Giving up or reducing activities because of opioid use
8. Using opioids in physically hazardous situations such as driving while under the influence of opiates
9. Continued opioid use despite ongoing physical or psychological problem likely to have been caused or worsened by opioids
10. Tolerance (i.e., need for increased amounts or diminished effect with continued use of the same amount) [b]
11. Experiencing withdrawal (opioid withdrawal syndrome) or taking opioids (or a closely related substance) to relieve or avoid withdrawal symptoms [b]

Abbreviations: DSM-5, Diagnostic and Statistical Manual for Mental Disorders, 5th edition; OUD, opioid use disorder.

Notes:

- a. American Psychiatric Association: [Opioid Use Disorder](#) [APA 2022].
- b. Tolerance and withdrawal criteria for OUD should not be applied if individual is taking prescribed opioids solely under medical supervision.

Use of other substances: Individuals should not be excluded from pharmacologic OUD treatment based on their use of other substances unless there are contraindications to the OUD medications and the risks outweigh the consequences of untreated OUD [Payne, et al. 2019; Cunningham(a), et al. 2013; Sullivan, et al. 2011]. Studies have demonstrated no significant differences in OUD treatment retention or self-reported opioid use in participants with OUD who used cocaine during the study compared with those who did not [Cunningham(a), et al. 2013; Sullivan, et al. 2011]. The U.S. Food and Drug Administration (FDA) issued a [Drug Safety Communication](#) in 2017 urging caution in withholding methadone or BUP from patients using benzodiazepines or alcohol, noting that the harm of not treating OUD outweighs the risk of adverse events associated with combining the medication. Co-occurring substance use may influence individual treatment plans but should not be the sole reason for excluding patients from pharmacologic OUD treatment.

Psychosocial treatment: Psychosocial treatment interventions for OUD can be useful adjuncts to pharmacologic treatment for some patients; however, clinical trial results have consistently demonstrated that pharmacologic treatment is more effective than nonpharmacologic treatment of OUD in reducing nonprescription opioid use, decreasing overdose risk, improving retention in care, and improving other psychosocial and medical conditions [Wakeman, et al. 2020; Fiellin, et al. 2013; Ruetsch, et al. 2012; Tetrault, et al. 2012; Amato(a), et al. 2011; Amato(b), et al. 2011; Weiss, et al. 2011; Humphreys, et al. 2004]. A lack of participation in structured psychosocial treatment for OUD should not prompt clinicians to withhold or discontinue pharmacologic treatment for OUD. When psychosocial treatment is mandated by the criminal justice system, child welfare, or other agencies, a clinician's primary responsibility is to maintain the therapeutic alliance and partner with the patient to address legal mandates.

OUD treatment initiation in the ED: Clinicians in EDs and inpatient hospital settings have many opportunities to reach individuals with OUD who are not linked to care. Clinicians should initiate pharmacologic OUD treatment in patients who have been treated for an opioid overdose or a complication related to opioid use before they are discharged from acute care and refer patients for OUD treatment. Clinicians in these settings should also dispense or prescribe NLX for patients who use opioids. Studies have demonstrated that initiating BUP treatment in the ED is feasible and cost-effective and can contribute to increased retention in care [Wakeman, et al. 2021; Englander, et al. 2019; Busch, et al. 2017; D'Onofrio, et al. 2017; D'Onofrio, et al. 2015; Liebschutz, et al. 2014]. The NYSDOH supports [MATTERS](#), an online platform for clinicians in acute care settings to facilitate linkage to care. For further guidance on providing BUP treatment in EDs and hospital settings, please see:

- American College of Emergency Physicians: [Consensus Recommendations on the Treatment of Opioid Use Disorder in the Emergency Department](#)
- Society of Hospital Medicine: [Management of Opioid Use Disorder and Associated Conditions Among Hospitalized Adults](#)

Treatment Options

ODU treatment history: Clinicians should obtain a complete history of previous OUD treatment to ensure that the patient’s experiences, preferences, and needs are incorporated into treatment decision-making. When asking patients about prior pharmacologic treatment, clinicians should inquire about tolerance of and success with medication initiation, experience with long-term treatment, adherence challenges, adverse effects, treatment duration, and reasons for stopping treatment [SAMHSA(b) 2021; ASAM 2020]. Prior experiences with pharmacologic treatment often shape preferences for specific medications; patients who have had negative experiences with 1 medication may prefer to try another [Yarborough, et al. 2016]. Clinicians should also inquire about self-treatment with nonprescribed medications (including BUP), which is prevalent among individuals trying to reduce opioid use or struggling to access, engage in, or stay engaged in treatment. In observational studies, prior use of nonprescribed BUP is associated with improved treatment retention [Williams, et al. 2022; Monico, et al. 2015; Cunningham(b), et al. 2013].

Available pharmacologic treatment: Clinicians should inform patients with OUD about all available pharmacologic treatment options and formulations and engage in shared decision-making about the best setting, medication, and formulation based on the individual patient’s treatment goals, preferences, and insurance coverage.

Currently, 3 medications are approved by the FDA for OUD treatment: methadone, BUP, and XR naltrexone. All 3 medications act on the mu-opioid receptor: methadone as a full opioid agonist, BUP as a partial opioid agonist, and naltrexone as an opioid antagonist. The preferred agents for treatment of OUD are BUP and methadone. Decades of clinical research support the efficacy of opioid agonist medications in reducing nonprescription opioid use and improving retention in treatment among individuals with OUD. BUP and methadone are both associated with up to 50% reduction in risk of all-cause and overdose-related mortality [Mattick, et al. 2014; Minozzi, et al. 2011; Ling and Wesson 2003; Mello and Mendelson 1980; Dole and Nyswander 1965]. Methadone is associated with higher rates of long-term treatment retention than BUP [Degenhardt, et al. 2023], but BUP is more widely available than methadone. Treatment planning, therefore, requires consideration of the relative differences in long-term treatment retention along with a patient’s previous experience, access, and preferences. For a discussion of each medication, see the guideline sections [Buprenorphine/Naloxone](#), [Methadone](#), and [Naltrexone](#).

Many individuals with OUD achieve their treatment goals in outpatient primary care-based settings. When available, specialty OUD treatment settings (e.g., outpatient treatment programs, opioid treatment programs [OTPs]) that provide pharmacologic treatment along with frequent visits, individual and group counseling, and other supportive services may benefit some individuals, including those with co-occurring SUDs, mental health needs requiring intensive treatment, or inadequate psychosocial supports.

Treatment selection based on individual factors: Many individual patient factors influence OUD treatment choice, including prior treatment experience, ease of access, and preferences (see Table 1, below). Pharmacologically, 2 key factors are the patient’s opioid tolerance and co-occurring medical conditions. Patients with low opioid tolerance who wish to initiate opioid agonist treatment may benefit from BUP rather than methadone because, as a partial opioid agonist, BUP carries a lower risk for sedation. Methadone is associated with QT prolongation and respiratory depression, so may not be preferred for patients with cardiac conduction disorders or severe respiratory conditions [FDA 2014].

Although many individuals with OUD can be treated with BUP/NLX in the primary care setting, some have clinical challenges that warrant consultation with experts in addiction medicine, obstetrics, adolescent care, pain management, and other medical specialties. Consultation may be necessary when, for instance, managing the care of patients with chronic pain or patients who have ongoing nonprescription opioid use or cravings despite taking the maximum FDA-approved dose (BUP/NLX 24 mg/6 mg daily). Doses of BUP up to 32 mg daily may be indicated to relieve opioid craving and promote treatment retention, particularly in individuals with chronic fentanyl exposure [Baxley, et al. 2023; Grande, et al. 2023; Weimer, et al. 2023; Bergen, et al. 2022]. Alternatively, switching to long-acting injectable XR-BUP may address opioid use and cravings because this formulation delivers a higher steady-state plasma concentration of BUP than sublingual BUP/NLX [Weimer, et al. 2023]. In these and other complex situations, clinicians can contact expert consultants through the NYSDOH AI [CEI Line](#) (866-637-2342) and [Providers Clinical Support System](#).

Long-term treatment: Several randomized clinical trials have demonstrated that long-term pharmacologic treatment is more effective at reducing nonprescription opioid use and retaining individuals in treatment than withdrawal management (previously known as “detox”) [Fiellin, et al. 2014; Sigmon, et al. 2013; Weiss, et al. 2011; Gruber, et al. 2008; Woody, et al. 2008]. In addition, withdrawal management without concurrent use of pharmacologic long-term therapy is associated with an increased risk of return to opioid use, overdose, and death [Dowell, et al. 2022; SAMHSA(b) 2021; Bruneau, et al. 2018]. A decreased tolerance to opioids developed during withdrawal management increases the risk of opioid overdose [Kampman

and Jarvis 2015]. Despite clear evidence supporting the benefits of long-term pharmacologic treatment, further research to guide the specific duration is needed [Dhanda and Salsitz 2021].

Individualized follow-up: After initiating treatment for OUD, follow-up patient contact and scheduling is based on the medication patients are taking and their individual needs. For patients taking BUP/NLX or XR naltrexone in an outpatient primary care setting, following up within 2 weeks of treatment initiation allows the clinician to tailor the treatment plan (e.g., change in medication dosage, addition of support services) to a patient’s needs and provide encouragement. As patients stabilize on BUP/NLX treatment, monthly or at least quarterly follow-up allows for ongoing evaluation to ensure that their goals are being met. For patients taking XR naltrexone, scheduled injections every 28 days are an opportunity to review the treatment plan and address any concerns. For methadone treatment, follow-up frequency is determined by clinical assessment of overdose risk and state and federal regulations governing OTPs.

During long-term treatment, ongoing follow-up is essential for support, encouragement, and modification of the treatment plan as needed. As with the treatment goals for other chronic illnesses, OUD treatment goals are individualized and likely to change over time, and continued engagement in nonjudgmental, health-enabling support can aid in the progression toward healthy goals. Clinicians and patients should discuss, agree on, and revisit OUD treatment goals explicitly and regularly. In general, if patients are not able to meet their goals, increased dosing of medication, more frequent visits, behavioral interventions, and/or mental health assessment and treatment may be warranted.

Table 1: Considerations When Choosing Buprenorphine or Methadone (Preferred Agents for Opioid Use Disorder Treatment)		
Consideration	Buprenorphine	Methadone
Effectiveness	Treatment of OUD with BUP or methadone is associated with reducing other opioid use, promoting treatment retention, and reducing all-cause and overdose-related mortality.	
Patient preferences	May be preferable for patients who are new to pharmacologic OUD treatment, have had previous success with BUP, do not like or want to take methadone, or who have requested this medication.	May be preferable for patients who have had previous success with methadone, do not like or want to take BUP, or who have requested this medication.
Setting	Available through various treatment settings, including office-based prescription or specialty OTPs.	<ul style="list-style-type: none"> Available only through a specialty OTP or a mobile medical unit (in New York State). Effective for 1 year after the end of the COVID-19 Public Health Emergency, OTPs have increased flexibility to provide unsupervised take-home doses of methadone, potentially up to 28-day supplies, depending on the patient’s time in treatment and the OTP clinician’s assessment of therapeutic risks and benefits.
Initiation	<ul style="list-style-type: none"> Opioid withdrawal is required for standard initiation. Low-dose BUP with opioid continuation (previously known as microdosing or micro-induction) is an alternative strategy that does not require onset of opioid withdrawal. 	Opioid withdrawal is not required for initiation.
Titration	<ul style="list-style-type: none"> Sublingual doses can be increased to an FDA-approved maximum of 24 mg per day to suppress opioid cravings and prevent withdrawal. Sublingual dose increases up to 32 mg daily may be indicated for individuals with ongoing withdrawal symptoms, cravings, or opioid use, but clear documentation of rationale and prior insurance authorization may be required. In New York, as of January 18, 2024, the state Medicaid program covers up to 32 mg BUP daily for OUD treatment without prior authorization. 	Dose can be increased gradually to suppress opioid cravings and prevent withdrawal, with no maximum dose.

Table 1: Considerations When Choosing Buprenorphine or Methadone (Preferred Agents for Opioid Use Disorder Treatment)

Consideration	Buprenorphine	Methadone
Adverse effects and safety	<ul style="list-style-type: none"> • Lower risk of respiratory depression and sedation than full-agonist opioids. • Opioid-related adverse effects can occur, including constipation and sleep-disordered breathing. 	<ul style="list-style-type: none"> • Higher risk of respiratory depression and sedation than partial-agonist opioids; dose with caution in patients with severe respiratory disease or who are taking methadone in combination with other sedating substances. • Associated with QT prolongation, particularly with history of arrhythmia, structural heart disease, or concurrent use of other QTc prolonging medications. • Opioid-related adverse effects can occur, including constipation and sleep-disordered breathing.
Medication interaction	Few clinically significant interactions with medications other than full opioid agonists.	Clinically significant interactions with medications that are metabolized by CYP450 enzymes can occur, leading to increased or decreased effects of methadone. <ul style="list-style-type: none"> • See Medscape: Drug Interaction Checker.
Counseling requirements	Not required unless legally mandated, but clinicians can refer for behavioral therapy and support services.	<ul style="list-style-type: none"> • Specialty OTPs offer more structured counseling and support services than primary care settings. • In New York State, psychosocial counseling is not required for methadone treatment.
Treatment switch	Switching to XR-BUP or methadone is possible if needed to control opioid cravings and withdrawal despite maximized sublingual BUP dosing.	<ul style="list-style-type: none"> • Can be considered when benefits outweigh risks. • Closely monitor switch to BUP because of the potential for precipitated withdrawal.

Abbreviations: BUP, buprenorphine; CYP450, cytochrome P450; FDA, U.S. Food and Drug Administration; OTP, opioid treatment program; OUD, opioid use disorder; XR, extended-release.

Buprenorphine/Naloxone

RECOMMENDATIONS

BUP/NLX: Preferred Treatment

- Clinicians should recommend coformulated BUP/NLX as a preferred treatment for individuals with OUD. (A1) See [Table 1: Considerations When Choosing Buprenorphine or Methadone \(Preferred Agents for Opioid Use Disorder Treatment\)](#).

BUP/NLX Initiation

- **Initiation setting:** Because both home-based (unobserved) initiation and office-based (observed) initiation are effective, clinicians should advise an initiation setting based on patients' experience, comfort, and preferences and clinicians' practice experience and support. (B2)
- **Precipitated withdrawal:** Clinicians should assess the potential for, educate patients about, and have a clear protocol for managing precipitated withdrawal. (A3)
- **Standard initiation:** To minimize the risk of precipitated withdrawal, clinicians should advise patients to wait for the onset of mild to moderate opioid withdrawal before starting BUP/NLX treatment. (A2)
 - As indicated, clinicians should provide adjunctive medications to relieve specific symptoms of acute opioid withdrawal (B2). See [Table 2: Adjunctive Medications to Relieve Acute Opioid Withdrawal Symptoms](#).

RECOMMENDATIONS

- **Low-dose BUP with opioid continuation** (LDB-OC; previously known as microdosing or micro-induction): For patients who may be unable to tolerate opioid withdrawal before starting BUP/NLX, or for patients who have had prior experience with precipitated withdrawal with standard initiation, clinicians should offer LDB-OC as an alternative initiation approach. (A2)

BUP/NLX Dosing

- Clinicians should titrate BUP/NLX to the dose needed to control patients' cravings, reduce or prevent withdrawal symptoms, and support treatment goals. (A3) See [Table 3: Buprenorphine/Naloxone for Treatment of Opioid Use Disorder in Nonpregnant Adults](#).
- If a patient has continued symptoms of opioid withdrawal, cravings, or opioid use despite the maximum dose of BUP/NLX approved by the FDA (24 mg/6 mg daily), the clinician should pursue 1 or more of the following strategies:
 - Ensure the patient is taking the medication as prescribed [a]. (A3)
 - Increase the total daily dose of BUP up to 32 mg, particularly for patients with chronic fentanyl exposure, and reassess the need for higher (>24 mg daily) long-term dosing when patients have stabilized. (A2)
 - Offer adjunctive medication and psychosocial treatment to relieve specific symptoms that persist after acute opioid withdrawal, known as protracted withdrawal or post-acute withdrawal syndrome. (B3)
 - Offer long-acting injectable BUP. (A2)
 - Offer referral to methadone treatment if available and preferred by the patient. (A3)
- If a patient chooses to discontinue BUP/NLX treatment, the clinician should:
 - Discuss alternative medication, including methadone and naltrexone. (A1)
 - Inform the patient about the risks of recurrence of use, reduced tolerance, and opioid overdose. (A3)
 - Offer the patient a slow, tapering decrease schedule to minimize withdrawal symptoms. (B3)
- Clinicians should consult with or refer the patient to a clinician experienced in treatment of SUD if encountering challenges with BUP/NLX dosing (e.g., increases beyond the FDA-approved maximum dose), switching to long-acting injectable BUP, or tapering or discontinuing treatment. (A3)

Abbreviations: BUP, buprenorphine; FDA, U.S. Food and Drug Administration; NLX, naloxone; OUD, opioid use disorder; SUD, substance use disorder.

Note:

- a. BUP/NLX should be dissolved under the tongue rather than swallowed.

Efficacy

Although BUP was developed initially as an analgesic, it was identified several decades ago as an alternative to methadone for OUD treatment [Institute of Medicine 1995; Mello and Mendelson 1980; Jasinski, et al. 1978]. BUP is a partial opioid agonist with a higher affinity for the mu-opioid receptor than heroin, methadone, and other opioids. It can displace full opioid agonists from mu-opioid receptors and replace them with partial activation. The opioid effect (or “ceiling effect”) of BUP is less intense than the effect produced by methadone or heroin. The high affinity of BUP for the mu-opioid receptor also has protective effects against opioid overdose. If a patient taking BUP/NLX takes a full opioid agonist, BUP will block the other opioid from activating mu-opioid receptors and prevent more intensive opioid effects, such as respiratory depression.

Extensive clinical trials and systematic reviews have demonstrated that, compared with placebo, BUP significantly reduces use of nonprescription opioids and improves retention in treatment [Mattick, et al. 2014; Amato, et al. 2005; Ling and Wesson 2003; Mattick, et al. 2003]. BUP treatment has also been associated with decreased risks of both all-cause and opioid overdose mortality [Ma, et al. 2019; Laroche, et al. 2018; Sordo, et al. 2017; Schuckit 2016]. A systematic review of clinical trials and observational studies found that BUP treatment is associated with a lower rate of long-term treatment retention than methadone treatment [Degenhardt, et al. 2023]. Nonetheless, the relative differences in long-term treatment retention between BUP and methadone should be considered in the context of patient preferences and treatment access, with BUP being more widely available.

Formulations

Sublingual BUP/NLX: BUP is most commonly available as coformulated BUP/NLX in sublingual films or sublingual tablets, which contain 2 mg to 8 mg of BUP per film or tablet [Mattick, et al. 2014; Ling and Wesson 2003]. Sublingual BUP/NLX is typically taken as 1 dose or split into 2 to 3 doses daily, depending on the patient's need for co-occurring pain management. Sublingual BUP/NLX is generally prescribed through community pharmacies for patients to self-administer.

Sublingual BUP: BUP is also available as monoformulated sublingual tablets. However, the BUP/NLX coformulation is recommended over the BUP monoformulation because it is less likely to be misused. When BUP/NLX is taken sublingually, only a negligible amount of NLX, if any, is bioavailable and clinically active. However, when BUP/NLX is injected, NLX is fully bioavailable and will delay the euphoric effects of BUP in individuals who do not already have physical dependence on opioids. Thus, the BUP/NLX coformulation serves as a deterrent to medication misuse. However, most diverted or misused BUP is used for OUD self-treatment and not for euphoria [Carroll, et al. 2018]. BUP/NLX coformulation is preferred over BUP monoformulation except in patients with hypersensitivity or allergies to NLX, which are extremely rare in clinical experience.

Injectable XR-BUP: Long-acting BUP (XR-BUP) is available as a weekly or monthly subcutaneous depot injection [Lofwall, et al. 2018]. Weekly injectable XR-BUP can be used to initiate BUP treatment in patients who are not already taking BUP; injections should be initiated immediately after a test dose of sublingual BUP to demonstrate tolerance without precipitated withdrawal. Monthly injectable XR-BUP is typically used with patients who have initiated treatment with a sublingual BUP dosage of 8 mg or higher for a minimum of 7 days, although varying initiation approaches can be used under specialist guidance.

XR-BUP must be obtained through pharmacies that are certified by the XR-BUP manufacturer's restricted distribution program (see [Sublocade REMS \[Risk Evaluation and Mitigation Strategy\]](#) and [Brixadi REMS](#)). The medication is delivered to the prescriber's practice by the REMS-certified pharmacy in anticipation of a patient's injection appointment. Clinical programs or healthcare settings that wish to stock XR-BUP onsite must be certified in the XR-BUP manufacturer's REMS. [Brixadi \(BUP\)](#) was approved by the FDA in May 2023 for OUD treatment as weekly or monthly injections and became available in fall 2023.

XR-BUP may be preferred to sublingual BUP/NLX for some patients with OUD, although evidence is just beginning to accrue. XR-BUP can achieve more stable and higher plasma levels than sublingual BUP [Radosh, et al. 2022], which may be beneficial for patients with high opioid tolerance or with ongoing opioid withdrawal symptoms or cravings while taking the maximum daily dosage of sublingual BUP. XR-BUP may also improve treatment outcomes for patients who have difficulty adhering to daily dosing. In a randomized clinical trial, patients who initiated XR-BUP before release from jail had higher treatment retention than those receiving BUP/NLX [Lee, et al. 2021]. An observational study found high treatment retention rates among patients who received XR-BUP, even when most did not have stable housing [Peckham, et al. 2021]. In another recent randomized trial from Australia, XR-BUP was associated with higher patient satisfaction scores than sublingual BUP/NLX, although this study involved at least weekly visits and observed dosing for BUP/NLX [Compton and Volkow 2021].

Insurance coverage: In New York State, as of March 2022, all formulations of BUP prescribed to treat OUD are covered under Medicaid fee-for-service and managed plans (see [NYRx Medication Assisted Treatment \[MAT\] Formulary](#)).

Opioid Withdrawal

The length of time after a full opioid agonist is stopped and withdrawal starts depends on the opioid's pharmacologic properties. Known half-lives of full opioid agonists indicate that it may take at least 12 to 24 hours after the last dose of a short-acting opioid and at least 48 to 72 hours after the last dose of a long-acting opioid for a patient to experience opioid withdrawal symptoms. Although these time frames help set clinical expectations, individual experiences of opioid withdrawal may vary, and clinical management should be individualized.

Opioid withdrawal symptoms include increased heart rate, increased sweating, dilated pupils, restlessness, bone or muscle aches, muscle twitches or tremors, runny nose or tearing, gastrointestinal upset (nausea, vomiting, cramps, diarrhea), anxiety, irritability, goosebumps on skin, hot flushes or chills, and yawning. Clinical tools available to measure the severity of opioid withdrawal include the [Clinical Opiate Withdrawal Scale](#) and the [Subjective Opiate Withdrawal Scale](#) [Wesson and Ling 2003; Handelsman, et al. 1987]. Clinicians can offer adjunctive medications, including clonidine, loperamide, and trazodone, to alleviate specific opioid withdrawal symptoms (see Table 2, below).

A patient’s recent opioid use history and review of the NYSDOH [Prescription Monitoring Program \(PMP\) Registry](#) will help clinicians and patients anticipate withdrawal symptoms. Methadone and BUP dispensed from opioid treatment programs (OTPs) will not be included in the PMP.

Precipitated opioid withdrawal: BUP can displace full opioid agonists from mu-opioid receptors and replace them with partial activation. Before starting a patient on BUP/NLX, assess for and inform the patient about the potential for precipitated opioid withdrawal, the symptoms they may experience, and how those symptoms will be managed [Cunningham, et al. 2011; Sohler, et al. 2010; Lee, et al. 2009]:

- Educate all patients about expected withdrawal symptoms and distinguishing precipitated withdrawal as a sudden worsening of symptoms immediately after BUP/NLX initiation.
- Identify individuals with chronic fentanyl exposure; their risk of precipitated withdrawal may be greater than the risk for patients without chronic fentanyl exposure (see discussion of opioid withdrawal considerations in the context of chronic fentanyl exposure, below).
- Ensure that patients understand the potential severity of precipitated withdrawal symptoms and when to seek medical consultation. Provide patients with a clear plan of response to precipitated withdrawal, including how to contact a clinician.
- If precipitated withdrawal occurs:
 - If the patient wants to continue BUP/NLX initiation, advise them to take additional higher doses (e.g., 8 mg/2 mg to 16 mg/4 mg per dose) and provide adjunctive medications for symptom management.
 - If the patient decides to stop BUP/NLX initiation, engage the patient in shared decision-making regarding alternative treatment options and initiation strategies.

Opioid withdrawal considerations in the context of chronic fentanyl exposure: The onset and duration of opioid withdrawal may be variable and prolonged in individuals with chronic fentanyl exposure [Huhn, et al. 2020]. Pharmacologically, the risk of precipitated withdrawal during BUP initiation is higher with fentanyl than with heroin because of fentanyl’s high opioid receptor affinity, lipid solubility, and intrinsic agonist activity [Greenwald, et al. 2022]. People who regularly use heroin and fentanyl report increasing experiences of precipitated withdrawal and difficulty with standard BUP/NLX initiation, particularly when BUP is initiated within 24 hours of fentanyl use [Sue, et al. 2022; Varshneya, et al. 2022; Silverstein, et al. 2019]. In contrast, a recent prospective cohort study of patients who presented to the emergency department (ED) for opioid withdrawal reported a very low incidence of precipitated withdrawal after receiving BUP initiation doses of ≥8 mg, despite high rates of heroin and fentanyl use [D’Onofrio, et al. 2023].

Although precipitated withdrawal is a serious concern, BUP can be initiated successfully with effective patient education and support. Continue to offer BUP, discuss patient concerns regarding BUP initiation, and consider an alternative BUP initiation strategy for patients who cannot tolerate opioid withdrawal or who have experienced precipitated withdrawal with standard initiation methods. Alternative strategies include:

- Low-dose BUP with opioid continuation (LDB-OC; previously known as microdosing or micro-induction) with an initial BUP dose of <2 mg and gradual up-titration while continuing full opioid agonist for a limited period; initiation does not require onset of opioid withdrawal (see guideline section Initiating Treatment, below) [Cohen, et al. 2022].
- High-dose initiation with an initial BUP dose of > 8 mg and rapid up-titration within 1 day; initiation requires onset of opioid withdrawal [D’Onofrio, et al. 2023; Snyder, et al. 2023; Herring, et al. 2019].

Current evidence and expert opinion favor the LDB-OC approach to BUP initiation in the outpatient setting, where patients are often evaluated when they are not in opioid withdrawal or are in mild withdrawal. Published experience with high-dose initiation has been with patients with moderate to severe opioid withdrawal evaluated in the ED [D’Onofrio, et al. 2023; Snyder, et al. 2023; Herring, et al. 2019], and further research is needed to guide its use in an ambulatory setting.

Table 2: Adjunctive Medications to Relieve Acute Opioid Withdrawal Symptoms

Reprinted with permission from [Torres-Lockhart, et al. 2022]

Withdrawal Symptom	Medication/Class	Preferred Route/Dosage/Considerations
Autonomic hyperactivity, including muscle twitching, hot flushes or chills, restlessness	Clonidine (α-2 agonist)	<ul style="list-style-type: none"> • Oral, 0.1 to 0.3 mg ≤4 times daily • Monitor blood pressure and heart rate after initial dose and before up-titration • Not FDA-approved for opioid withdrawal management
	Lofexidine (α-2 agonist)	<ul style="list-style-type: none"> • Oral, 0.54 mg ≤4 times daily • FDA-approved for opioid withdrawal management; costly

Table 2: Adjunctive Medications to Relieve Acute Opioid Withdrawal Symptoms

Reprinted with permission from [Torres-Lockhart, et al. 2022]

Withdrawal Symptom	Medication/Class	Preferred Route/Dosage/Considerations
Diarrhea	Loperamide (peripheral μ opioid agonist)	<ul style="list-style-type: none"> Oral, 4 mg followed by 2 mg as needed for each loose stool (up to 16 mg daily) Ensure adequate oral hydration
Insomnia	Trazodone (sedating anti-depressant)	Oral, 25 to 100 mg once daily at night
	Doxepin (sedating anti-depressant)	Oral, 10 to 50 mg once daily at night
Muscle aches, joint pain, headache	Ibuprofen (NSAID)	<ul style="list-style-type: none"> Oral, 400 to 600 mg at least every 6 hours Avoid use in patients with severe kidney disease and decompensated cirrhosis
	Acetaminophen (aniline analgesic)	<ul style="list-style-type: none"> Oral, 650 to 1,000 mg at least every 6 hours Use with caution in liver disease
Anxiety, restlessness	Diphenhydramine (antihistamine)	<ul style="list-style-type: none"> Oral, 25 to 50 mg at least every 4 hours Can help with nausea Can be used during pregnancy
	Hydroxyzine (antihistamine)	<ul style="list-style-type: none"> Oral, 25 to 100 mg at least every 6 hours Can help with lacrimation and rhinorrhea

Abbreviations: FDA, U.S. Food and Drug Administration; NSAID, nonsteroidal anti-inflammatory drug.

Initiating Treatment

Setting: Home-based (unobserved) and office-based (observed) initiation of BUP/NLX treatment are safe and effective [Cunningham, et al. 2011; Gunderson, et al. 2010; Sohler, et al. 2010; Lee, et al. 2009]. The choice of setting is based on the patient’s comfort, preferences, and previous experience, as well as a clinician’s experience and support. The primary concern during initiation is precipitating opioid withdrawal, which can be deeply uncomfortable but can be ameliorated outside of an observed clinical setting (see guideline section Opioid Withdrawal, above). Individuals with OUD who are not in treatment may experience withdrawal symptoms regularly between doses of opioids over many years; patients’ familiarity with opioid withdrawal may be leveraged to help counsel and support them through home-based initiation. A patient’s preferences in managing their medications, including dividing BUP/NLX tablets or films into smaller doses, and access to telehealth for frequent check-ins can facilitate successful home-based initiation. Alternatively, observed initiation may be preferable for patients who do not have a safe space to prepare and store medications or manage potential withdrawal symptoms.

→ KEY POINTS

- Clinicians can contact expert consultants in OUD treatment through the following:
 - [CEI Line](tel:866-637-2342): 866-637-2342
 - [Providers Clinical Support System](#)
- The NYSDOH [PMP Registry](#) must be consulted before providing each prescription for BUP/NLX. The database tracks individuals’ history of pharmacy-dispensed controlled substances, but it does not include medications dispensed in OTPs.

Standard initiation: The goals of treatment initiation are to control the patient’s opioid cravings, reduce withdrawal symptoms, and reduce nonprescription opioid use. With the standard approach to BUP/NLX initiation, the patient should experience mild to moderate withdrawal before the first dose is administered (see Table 3, below). The initial dose of BUP/NLX is typically 2 mg/0.5 mg to 4 mg/1 mg and is titrated every 1 to 2 hours in increments of 2 mg/0.5 mg to 4 mg/1 mg until the patient’s withdrawal symptoms improve. Advise patients to allow time (e.g., a few hours) for opioid withdrawal symptoms to improve after BUP/NLX initiation. The total dose of BUP/NLX taken on day 1 should be administered on day 2, with incremental dose increases if the patient continues to experience opioid withdrawal symptoms or cravings. The BUP/NLX dose typically stabilizes between days 2 to 7 during the standard initiation process, and the maximum dose of

BUP/NLX is typically 24 mg/6 mg per day. For patient education on initiation, see the [Addiction Training Institute: A Guide for Patients Beginning Buprenorphine Treatment](#).

Treatment may be initiated with higher doses of BUP/NLX (e.g., 4 mg/1 mg to 8 mg/2 mg) if a patient has prior experience with BUP/NLX, with dose titration up to BUP/NLX 24 mg/6 mg on the first day. Patients who are transitioning from long-acting opioids, such as methadone, to BUP/NLX may be at higher risk for complications during the standard initiation process [Whitley, et al. 2010]. Consulting with an experienced clinician may help determine the optimal initiation approach.

→ KEY POINTS

- BUP/NLX is generally initiated after the onset of mild to moderate opioid withdrawal symptoms and titrated in incremental doses. The goal is to reach a dose that will control a patient's opioid cravings, reduce or prevent withdrawal symptoms, and support the patient's treatment goals.
- Patients with chronic fentanyl exposure or other risk factors for precipitated withdrawal may benefit from low-dose BUP with opioid continuation (LDB-OC), in which full opioid agonists can be continued until a therapeutic level of BUP is achieved. Discussion and documentation of the risks of ongoing nonprescribed full opioid agonist use and strategies to maximize safe use is essential.

Low-dose BUP with opioid continuation (LDB-OC): This approach, which does not require waiting for onset of opioid withdrawal, may be appropriate for patients who are unable to tolerate waiting for onset of opioid withdrawal, have experienced precipitated withdrawal with standard initiation methods, are receiving full opioid agonist treatment for acute or chronic pain, or are receiving methadone treatment for OUD. Treatment may be initiated with a very low dose of BUP (e.g., 0.2 mg to 0.5 mg), followed by small incremental dose increases over 4 to 10 days. Patients can continue to take other full opioid agonists, including nonprescribed opioids until a therapeutic level of BUP is reached (typically >8 mg). Case reports on use in nonpregnant adults indicate that low-dose initiation is well tolerated and may reduce severity of withdrawal symptoms during BUP/NLX initiation [Cohen, et al. 2022; Adams, et al. 2021; Ahmed, et al. 2021; Hämmig, et al. 2016].

Although high-quality evidence comparing the effectiveness of standard versus low-dose initiation strategies is not yet available to guide clinical care, different methods for LDB-OC have been described, with starting doses varying by availability of formulations and treatment settings. Table 4, below, provides an example of an outpatient protocol based on clinical review articles and the author's experience at Montefiore Medical Center [Cohen, et al. 2022; Peterkin, et al. 2022]. Protocols can be individualized and can be shorter or longer in duration based on patients' comfort and clinicians' experience. Clinicians may wish to seek expert consultation in individualizing a treatment plan.

There are no strong data available to help patients use nonprescribed opioids safely during the BUP/NLX initiation process. A discussion of treatment should address the risks of ongoing use and strategies to maximize safety, including safer use practices and overdose prevention (see NYSDOH AI guideline [Substance Use Harm Reduction in Medical Care](#)).

For patients taking methadone and planning to switch to BUP, safely continuing methadone treatment during low-dose BUP/NLX initiation can be done via coordination of care with the OTP. Some OTPs can oversee the low-dose initiation process before transferring BUP treatment to primary care settings.

Clear instructions to guide a patient through low-dose BUP/NLX initiation should include: 1) when and how to split films or tablets; 2) how to manage daily dosing changes; 3) how much and how long to continue use of full opioid agonists; and 4) when and how to follow-up on concerns during the initiation process. Low-dose initiation requires splitting the BUP/NLX 2 mg/0.5 mg films or tablets. A quarter of a film or tablet is a 0.5 mg BUP dose; half of a film or tablet is a 1 mg BUP dose. When possible, arranging for a pill box during an office visit or coordinating with a pharmacy to blister pack BUP/NLX can be very beneficial.

→ KEY POINT

- Arranging for close follow-up by phone or in person throughout the initiation process is essential to patient success; follow-up may involve daily phone check-ins and in-person follow-up within 1 week of BUP/NLX initiation.

Maximum daily BUP/NLX dose: Although the maximum daily FDA-approved dose of sublingual BUP/NLX is 24 mg/6 mg, a higher dose of up to 32 mg/8 mg daily may be beneficial for some patients, including those with a high degree of opioid dependence who continue to experience withdrawal symptoms or cravings [Baxley, et al. 2023; Grande, et al. 2023; Weimer, et al. 2023; Bergen, et al. 2022].

Before increasing the BUP/NLX dose beyond 24 mg/6 mg, clinicians should ensure that the patient is taking the medication as scheduled and is following the instruction to allow the pill to dissolve fully under the tongue rather than swallowing. Clinicians can also counsel patients to split the BUP/NLX for dosing 2 or 3 times per day. Dose increases above the FDA-approved maximum require close monitoring for treatment effectiveness and safety; documentation explaining the clinical rationale for such dose increases is advised given the potential need for prior insurance authorization. In New York, as of January 18, 2024, the state [Medicaid](#) program covers up to 32 mg BUP daily for OUD treatment without prior authorization.

As indicated, clinicians should also offer medication and psychosocial treatment to manage specific symptoms that may persist after acute opioid withdrawal (also referred to as protracted withdrawal or post-acute withdrawal syndrome), including anxiety, depression, and sleep disturbances (see SAMHSA: [Substance Abuse Treatment Advisory: Protracted Withdrawal](#)) [SAMHSA 2010]. Other strategies for managing continued opioid withdrawal symptoms or cravings include the use of injectable XR-BUP or referral for methadone treatment, if available. Consulting with or referring the patient for consultation with an experienced substance use clinician may be needed to optimize the next steps of OUD treatment.

Adverse effects: Adverse effects associated with BUP/NLX are oral hypoesthesia (sensitivity), glossodynia (burning sensation in the mouth), oral mucosal erythema, headache, nausea, vomiting, hyperhidrosis (excessive sweating), constipation, signs and symptoms of withdrawal, insomnia, pain, and peripheral edema [FDA 2010]. The bitter or bad taste of BUP/NLX is a frequent patient complaint in clinical practice; patients can be counseled to spit out their saliva or take a strong mint after BUP/NLX is fully dissolved. See [prescribing information](#) for full details.

Table 3: Buprenorphine/Naloxone for Treatment of Opioid Use Disorder in Nonpregnant Adults [a,b,c]		
Formulations and Mechanism of Action	Dosing (individualized as indicated)	Considerations for Use
<p>BUP/NLX sublingual film and tablet (multiple brands; see Medscape: Buprenorphine/Naloxone for more information)</p> <p>Mechanism: Partial opioid agonist</p>	<ul style="list-style-type: none"> • Standard initiation: <ul style="list-style-type: none"> – Initial BUP dose: 2 mg to 8 mg once patient is experiencing mild to moderate opioid withdrawal – Titration: Increase BUP dose every 1 to 2 hours by increments of 2 mg to 4 mg over 2 to 7 days until opioid cravings and withdrawal symptoms are controlled. • LDB-OC (previously known as microdosing or micro-induction): <ul style="list-style-type: none"> – Initial BUP dose: 0.25 mg to 0.5 mg while patient continues taking full opioid agonist [d] – Titration: Increase with low-dose increments of BUP over 7 days to reach therapeutic level; discontinue full opioid agonist. • Long-term treatment: The maximum dose of BUP is typically 24 mg taken once daily. <ul style="list-style-type: none"> – Increasing the dose up to 32 mg daily may be indicated for individuals with ongoing withdrawal, cravings, or opioid use. – The individualized dose that is most effective in supporting treatment goals should be continued as long-term treatment. – The total BUP dose can be divided by 2 or 3 for dosing throughout the day per patient preference. 	<ul style="list-style-type: none"> • Standard initiation: Confirm opioid withdrawal symptoms and severity by observation or patient report before starting BUP/NLX. • Ensure that the patient understands the dosing schedule and how to take BUP/NLX: avoid swallowing and let the medication dissolve under the tongue. • LDB-OC: Does <i>not</i> require opioid withdrawal and can be an alternative for patients who may not be able to tolerate standard initiation. <ul style="list-style-type: none"> – Individualized patient protocols, pharmacy blister packing, and care coordination with close follow-up are essential to success of low-dose initiation. – Expert consultation may be helpful to guide individualization and coordination of low-dose initiation. – Discuss the risks of ongoing nonprescribed opioid use and strategies to maximize safe use. – Ensure that the patient understands the dosing schedule, how to cut the medication into smaller doses, and to avoid swallowing and let the medication dissolve under the tongue. • Maximum dose: If a patient has opioid withdrawal symptoms or cravings that are not controlled by the FDA-approved BUP maximum dose of 24 mg daily, dosing up to 32 mg daily may be beneficial but may require insurance prior authorization. In New York, as of January 18, 2024, the state Medicaid program covers up to 32 mg BUP daily for OUD treatment without prior authorization.

Table 3: Buprenorphine/Naloxone for Treatment of Opioid Use Disorder in Nonpregnant Adults [a,b,c]		
Formulations and Mechanism of Action	Dosing (individualized as indicated)	Considerations for Use

<p>XR-BUP subcutaneous depot injections (multiple brands)</p> <p>Mechanism: Partial opioid agonist</p>	<p>Sublocade (monthly)</p> <ul style="list-style-type: none"> • Oral initiation: Patients should tolerate taking sublingual BUP ≥8 mg per day for ≥7 days prior to injection initiation [e]. • Injection initiation: Administer the first 300 mg injection at week 1, and the second 300 mg injection 4 weeks after the first. • Long-term treatment: Administer maintenance dose of 100 mg or 300 mg every 4 weeks. The monthly dose that is most effective in managing opioid cravings and supporting treatment goals should be continued as maintenance treatment. <p>Brixadi (weekly or monthly)</p> <ul style="list-style-type: none"> • Oral initiation: Administer a 4 mg sublingual dose to test BUP tolerance without precipitated withdrawal. • Injection initiation: <ul style="list-style-type: none"> – <i>For patients not already taking sublingual BUP,</i> administer a first dose of Brixadi 16 mg followed by an additional dose of 8 mg within 3 days of the first dose for a total weekly dose of 24 mg. An additional 8 mg dose can be administered at least 24 hours after the previous injection for a total weekly dose of 32 mg. – <i>For patients already taking sublingual BUP,</i> administer the corresponding dose of Brixadi weekly or monthly for the initial dose. See prescribing information for dose equivalents. • Long-term treatment: Dose is individualized with a maximum dose of 32 mg weekly or 128 mg monthly. 	<ul style="list-style-type: none"> • See manufacturers’ restricted distribution programs: Brixadi REMS (Risk Evaluation and Mitigation Strategy) or Sublocade Risk Evaluation and Mitigation Strategy (REMS). • Must be delivered from pharmacies or distributors that are certified by the manufacturer’s REMS. <p>Sublocade</p> <ul style="list-style-type: none"> • Store in refrigeration; can only be stored at room temperature for up to 12 weeks. • Administer subcutaneously in abdominal region. • Maintenance doses can be administered up to 2 weeks late without clinically significant impact. <p>Brixadi</p> <ul style="list-style-type: none"> • Store at room temperature. • Administer subcutaneously in the abdomen, buttock, or thigh. • After 4 consecutive injections in one of the sites noted above, the injection can be administered subcutaneously in the upper arm.
<p>Abbreviations: BUP, buprenorphine; DEA, Drug Enforcement Administration; FDA, U.S. Food and Drug Administration; LDB-OC, low-dose buprenorphine with opioid continuation; NLX, naloxone; OUD, opioid use disorder; REMS, Risk Evaluation and Mitigation Strategy; SAMHSA, Substance Abuse and Mental Health Services Administration; XR, extended-release.</p> <p>Notes:</p> <ol style="list-style-type: none"> Federal regulations effective in 2023 eliminated the waiver requirement for prescribing BUP. Any clinician with an active DEA license to prescribe controlled substances can prescribe BUP. To contact clinicians or programs who provide BUP for OUD treatment, call the HOPEline (1-877-8-HOPENY) (New York State), see NYC Health: Treatment for Opioid Use Disorder With Buprenorphine and Methadone > How to Find Treatment (New York City), or see SAMHSA: Buprenorphine Practitioner Locator. Consult full prescribing information for each medication before prescribing. For OUD treatment in pregnant individuals, see NYSDOH AI guideline Substance Use Disorder Treatment in Pregnant Adults. Low-dose initiation requires splitting the BUP/NLX 2 mg/0.5 mg films or tablets. A quarter of a film or tablet is a 0.5 mg BUP dose; half of a film or tablet is a 1 mg BUP dose. Under specialist guidance, XR-BUP initiation approaches may vary; in some patients, the first injection may be administered <7 days after starting sublingual BUP. 		

Table 4: Example Protocol for Outpatient Low-Dose Buprenorphine With Opioid Continuation [a,b]			
Day	Dosing of BUP [c]	Total Daily Dose of BUP	Full Opioid Agonist Use/ Administration
1	0.5 mg once daily	0.5 mg	Continue
2	0.5 mg twice daily	1 mg	Continue
3	1 mg twice daily	2 mg	Continue
4	2 mg twice daily	4 mg	Continue
5	3 mg twice daily	6 mg	Continue
6	4 mg twice daily	8 mg	Continue
7	8 mg AM and 4 mg PM	12 mg	STOP

Abbreviations: BUP, buprenorphine; NLX, naloxone.

Notes:

- This 7-day protocol is based on clinical review articles and the author’s clinical experience. Protocols should be individualized to the patient and can be shortened or extended in duration [Cohen, et al. 2022; Peterkin, et al. 2022].
- Low-dose BUP with opioid continuation was previously known as microdosing or micro-induction.
- Low-dose initiation requires splitting the BUP/NLX 2 mg/0.5 mg films or tablets. A quarter of a film or tablet is a 0.5 mg BUP dose; half of a film or tablet is a 1 mg BUP dose.

Approach to Tapering

There is no ideal duration for BUP/NLX treatment for OUD; long-term pharmacologic treatment is recommended over withdrawal management (previously known as “detox”); see guideline section [Treatment Considerations > Treatment Options](#). Studies published to date have not identified clear modifiable factors that predict optimal outcomes with BUP treatment. Based on committee expert experience, patients treated with BUP long-term in the primary care setting can successfully manage OUD for a decade or more without resuming use of nonprescription opioids.

If a patient has a clear desire to taper and stop BUP/NLX treatment, the clinician should ascertain the patient’s reasons for doing so. Some patients may associate long-term OUD treatment with the stigma of taking an opioid agonist [Bozinoff, et al. 2018]. If stigma is a predominant factor in a patient’s desire to stop BUP/NLX treatment, education regarding the chronic nature of OUD may help the patient accept the need for long-term medical management.

If a patient decides to discontinue BUP/NLX treatment, clinicians should provide harm reduction counseling and NLX to reduce the risks of recurrence of use and overdose. Counsel patients that with an interruption or decrease in use, their opioid tolerance has decreased, which increases the risk of overdose, and emphasize that they can restart pharmacologic treatment at any time.

Offer a slow taper over several months, and provide NLX at each encounter. There are limited data to guide the speed and duration of a BUP/NLX taper. In a retrospective cohort study, BUP/NLX tapering undertaken after at least 1 year of BUP treatment and a slow rate of taper (mean rate of ≤ 2 mg dose decrease per month over the taper period) were associated with reduced risk of opioid overdose [Bozinoff, et al. 2022]. A mean taper rate of ≤ 2 mg per month over the taper period was also associated with a reduced risk of return to opioid use [Bozinoff, et al. 2022]. In general, a reasonable approach is to reduce the daily dose of BUP/NLX by 10% to 20% per month. Providing a slow taper is likely to lead to less severe opioid withdrawal symptoms and may be easier for patients to tolerate than a rapid taper.

Methadone

RECOMMENDATIONS

Methadone: Preferred Treatment

- Clinicians should recommend methadone as a preferred treatment for individuals with OUD. (A1) See [Table 1: Considerations When Choosing Buprenorphine or Methadone \(Preferred Agents for Opioid Use Disorder Treatment\)](#).
- Methadone is available only through an OTP; therefore, the clinician should refer a patient for methadone treatment if methadone is preferred, if BUP/NLX is not available to the patient, or if the maximum dose of BUP/NLX does not control the patient's withdrawal symptoms or cravings. (A3)

Abbreviations: BUP, buprenorphine; NLX, naloxone; OTP, opioid treatment program; OUD, opioid use disorder.

Efficacy: Methadone is a full opioid agonist of the mu-opioid receptor. Full activation results in commonly known opioid effects, such as pain reduction, a sense of well-being or pleasure, and respiratory depression.

Clinical use of methadone for the treatment of OUD began in the 1960s [Jaffe, et al. 1969; Dole and Nyswander 1965], and numerous studies have demonstrated methadone's effectiveness in reducing nonprescription opioid use and improving retention in care compared with no treatment [Kampman and Jarvis 2015; Mattick, et al. 2014; Mattick, et al. 2009]. Methadone treatment has been associated with improvements in survival [Sordo, et al. 2017; Soyka, et al. 2011], reduction in HIV and hepatitis C virus acquisition and transmission [Lucas, et al. 2010], improvement in quality of life [Giacomuzzi, et al. 2003], improvement in birth-parent/fetal outcomes [Minozzi, et al. 2008], and reduction in criminal activity [Lind, et al. 2005].

Specialty OTPs: Methadone treatment for OUD is available only in specialty OTPs regulated by federal and state agencies. Regulations limit the number of patients that can be treated in each program and require observed dosing until patients are granted take-home doses based on established criteria. These restrictions have contributed to reduced access to methadone treatment for many individuals with OUD [SAMHSA(a) 2019; SAMHSA(b) 2019]. Effective for 1 year after the end of the COVID-19 Public Health Emergency, OTPs have increased flexibility to provide unsupervised take-home doses of methadone, potentially up to 28-day supplies, depending on the patient's time in treatment and the OTP clinician's assessment of therapeutic risks and benefits [SAMHSA 2024]. Flexibility in methadone take-home policies has not been made permanent, but studies show increased treatment engagement and patient satisfaction and no increases in overdose and diversion with take-home medication [SAMHSA 2024; Hoffman, et al. 2022; Amram, et al. 2021].

Clinicians should be aware of OUD treatment options in the patients' community and refer patients to an OTP when appropriate (see SAMHSA: [Opioid Treatment Program Directory](#) and [NYS OASAS Treatment Availability Dashboard](#)).

Because federal policies provide enhanced protection for individuals receiving substance use disorder (SUD) treatment (e.g., [Code of Federal Regulations > Confidentiality of Substance Use Disorder Patient Records](#)), clinicians should be aware that methadone dispensed from the OTP will not appear in the PMP; clinicians who are not affiliated with the OTP must also provide written patient consent to obtain information about treatment from the OTP. Communication between clinicians inside and outside of OTPs is important for many reasons, such as increased likelihood of identifying and managing potential drug-drug interactions and adverse effects (including central nervous system suppression) and overall health management.

Who to treat: Individuals who have a high tolerance for opioids or who have continued cravings while taking maximal doses of BUP/NLX may benefit from methadone, which is a full opioid agonist, to achieve optimal outcomes (see [Table 1: Considerations When Choosing Buprenorphine or Methadone \(Preferred Agents for Opioid Use Disorder Treatment\)](#)). Individuals with comorbidities, such as unstable serious mental illness or other untreated SUDs (e.g., alcohol use disorder or benzodiazepine use disorder), may benefit from an intensive treatment setting to optimize access to supportive services.

Adverse effects: Adverse effects associated with the use of methadone include constipation, lightheadedness, dizziness, sedation, nausea, vomiting, and sweating. Methadone use has been associated with life-threatening respiratory depression and QT prolongation [FDA 2014]. See [prescribing information](#) for full details.

Naltrexone

RECOMMENDATIONS

Naltrexone: Alternative Treatment

- Clinicians should offer XR naltrexone to patients with OUD who prefer naltrexone treatment or who are not able to access or meet their treatment goals with methadone or BUP/NLX. (A3)
- When informing patients about XR naltrexone as a treatment option, clinicians should emphasize the strong motivation and adherence required for success. (B1)
- Before administering XR naltrexone, clinicians should administer an NLX (or low-dose naltrexone) challenge and confirm that patients do not react to ensure that opioids have been cleared from the system. (A2) See [Table 5: Extended-Release Naltrexone for Treatment of Opioid Use Disorder in Nonpregnant Adults](#).

Abbreviations: BUP, buprenorphine; NLX, naloxone; OUD, opioid use disorder; XR, extended-release.

Efficacy

Naltrexone is an opioid antagonist (inhibitor) that binds to the mu-opioid receptor, causes no opioid effects, and fully blocks opioid agonists (heroin, methadone, and other opioids) from attaching to the mu-opioid receptor and causing opioid effects [Bisaga, et al. 2018]. Oral naltrexone is not approved by the U.S. Food and Drug Administration (FDA) for OUD treatment, although it is approved for the treatment of alcohol use disorder (see NYSDOH AI guideline [Treatment of Alcohol Use Disorder > Preferred Pharmacologic Treatment](#)).

Clinicians can use oral naltrexone to confirm that patients have been abstinent from opioids, to test whether patients can tolerate naltrexone before administering an XR injection, or to supplement XR naltrexone if patients experience cravings or withdrawal symptoms during the 28 days between naltrexone injections.

The long-acting injectable naltrexone formulation (XR naltrexone) became available in 2010. Studies have demonstrated that XR naltrexone is more effective than placebo for OUD treatment [Tiihonen, et al. 2012; Gastfriend 2011; Comer, et al. 2006], but only 2 randomized trials directly comparing BUP/NLX and XR naltrexone have been published to date [Lee, et al. 2018; Tanum, et al. 2017]. In 1 study conducted in the United States, participants randomized to receive BUP/NLX treatment had better outcomes, including higher treatment initiation rates and lower opioid return-to-use rates, than those randomized to receive XR naltrexone [Lee, et al. 2018]. In the other study, conducted in Norway, retention in treatment and the level of opioid use was similar in participants taking BUP/NLX and XR naltrexone [Tanum, et al. 2017]. Neither of these studies was conducted in a primary care setting; the U.S. study was conducted in community-based inpatient settings with outpatient follow-up, and the study in Norway was conducted in addiction clinics, where BUP/NLX was administered daily.

Furthermore, the risk of overdose among participants receiving XR naltrexone in the U.S. randomized controlled trial discussed above was nearly 4 times higher than the risk of overdose among those receiving BUP/NLX [Ajazi, et al. 2022]. Three large studies also found that XR naltrexone was not associated with decreased risk of overdose or all-cause mortality [Wakeman, et al. 2020; Morgan, et al. 2019; Laroche, et al. 2018]. Additionally, a large observational study found that participants with OUD who were treated with XR naltrexone were twice as likely to discontinue treatment after 30 days than those receiving BUP/NLX [Morgan, et al. 2018]. In 2019, the FDA issued a [warning letter](#) regarding the increased risk of overdose following cessation of naltrexone treatment for OUD [FDA 2019].

Who to Treat

Injectable XR naltrexone may be considered if BUP or methadone is not accessible or desired. Methadone and BUP are preferred over XR naltrexone because of the survival benefit associated with opioid agonist treatment among individuals with OUD [Wakeman, et al. 2020; Morgan, et al. 2019; Laroche, et al. 2018]. In particular, BUP/NLX is currently preferred over XR naltrexone based on the results of clinical trials [Lee, et al. 2018; Tanum, et al. 2017] (see discussion above), the practical challenges of initiating and maintaining XR naltrexone treatment, and the low number of patients who choose XR naltrexone over other options [Brooklyn and Sigmon 2017].

Initiating treatment with XR naltrexone requires patients to be fully withdrawn from opioids, which is difficult for many patients, particularly in outpatient settings. In the U.S. randomized controlled trial described above, 28% of participants

assigned to XR naltrexone did not complete the initiation phase versus only 6% assigned to BUP/NLX [Lee, et al. 2018]. The initiation process is likely part of the reason few patients choose to take XR naltrexone. In real-world practice, of 3,639 patients with OUD being treated in Vermont (where all treatment options are generally available), 2,565 were taking methadone, 1,055 were taking BUP, and 2 were taking XR naltrexone [Brooklyn and Sigmon 2017].

Clinicians should emphasize the need for adherence to XR naltrexone for OUD treatment. Clinical trials evaluating XR naltrexone for OUD treatment have demonstrated that adherence is essential to achieving a reduction in nonprescription opioid use and improving retention in treatment [Jarvis, et al. 2018; Lee, et al. 2018; Tanum, et al. 2017]. The initial clinical studies with XR naltrexone were performed among highly motivated individuals who were at risk of losing their jobs because of OUD [Saxon, et al. 2018]. A registry study found that factors associated with longer-term adherence were employment at baseline, private health insurance, normal mental status/minimal mental illness, school attendance, and less prior drug use [Saxon, et al. 2018].

Initiating Treatment

Before initiating XR naltrexone, inform patients of the following:

- There is a risk of prolonged opioid withdrawal if opioids are still in the patient's system when XR naltrexone is administered.
- Unlike BUP and methadone, XR naltrexone will not relieve withdrawal symptoms.
- There may be an increased risk of overdose if opioids are used after stopping treatment with XR naltrexone or toward the end of the 28-day dosing interval. Although overdose can occur when opioids are used after stopping any medication for OUD treatment, the risk is particularly high after stopping XR naltrexone, relative to BUP or methadone, because of the substantial reduction in opioid tolerance with XR naltrexone.

Prescribing information indicates that individuals should be abstinent from opioids for approximately 7 to 14 days before initiating XR naltrexone [FDA 2013]: 7 days for patients using short-acting opioids and 14 days for patients using long-acting opioids (e.g., methadone, XR formulations). During this period of opioid abstinence, individuals with OUD will experience moderate to severe withdrawal symptoms.

To confirm that an adequate length of time has passed since last opioid use ("washout period"), clinicians should perform an NLX challenge by administering intranasal NLX as available and observing the reaction (see Table 5, below). In individuals with recent opioid use, this may precipitate opioid withdrawal. If intranasal NLX is not available, consider a challenge with oral naltrexone, starting with a low dose (e.g., quarter of a 50 mg tablet or as available). If a patient is already taking oral naltrexone, an NLX challenge is not necessary.

In patients confirmed to have an adequate washout period but who have not previously tried naltrexone, a brief regimen of oral naltrexone can be used to confirm medication tolerance before administering the long-acting injectable formulation (see Table 5, below). Oral naltrexone is not approved by the FDA for OUD treatment, but it is used to initiate the treatment cycle for XR naltrexone. Alternatively, to shorten the initiation period for XR naltrexone, very low doses of naltrexone can be initiated in combination with a BUP taper without requiring a full opioid washout period [Bisaga, et al. 2018]. Oral naltrexone doses can be gradually titrated up to full blocking doses within 7 days to demonstrate naltrexone tolerance.

Once it is confirmed that a patient can tolerate naltrexone, an injection of XR naltrexone (380 mg intragluteal) may be administered every 28 days. It can be administered every 21 days if patients have breakthrough cravings. If injectable XR naltrexone is not immediately available, or if patients have breakthrough cravings during the cycle, oral naltrexone may also be taken.

Adverse effects: Adverse effects associated with XR naltrexone use include protracted withdrawal, nausea, vomiting, injection site reactions (including induration, pruritus, nodules, and swelling), muscle cramps, dizziness or syncope, somnolence or sedation, anorexia, decreased appetite, or other appetite disorders [FDA 2022]. See [prescribing information](#) for full details.

Table 5: Extended-Release Naltrexone for Treatment of Opioid Use Disorder in Nonpregnant Adults [a,b]		
Formulation and Mechanism of Action	Dosing	Considerations for Use
<p>XR naltrexone (Vivitrol)</p> <p>Mechanism: Opioid antagonist</p>	<p>Initial and long-term treatment (intragluteal injections): 380 mg every 28 days</p> <ul style="list-style-type: none"> Before starting XR naltrexone, confirm appropriate washout period from last opioid use with an NLX challenge: <ul style="list-style-type: none"> Administer intranasal NLX as available (e.g., 4 mg/0.1 mL) and observe the patient’s reaction. In individuals with recent opioid use, this may precipitate opioid withdrawal. If intranasal NLX is not available, consider use of oral naltrexone, starting with a low dose (e.g., a quarter of a 50 mg tablet). If a patient is already taking oral naltrexone, an NLX challenge is not necessary. Before administering the initial injection, inform patients of the potential adverse effects of naltrexone and initiate oral naltrexone. Advise the patient to: <ul style="list-style-type: none"> Take 25 mg of oral naltrexone (half of a 50 mg naltrexone tablet). After 1 hour, if no adverse effects are experienced, take another 25 mg of oral naltrexone (second half of the 50 mg tablet). If adverse effects are not experienced, take 50 mg of oral naltrexone once daily for 2 to 3 days. If adverse effects are experienced, stop taking oral naltrexone. 	<ul style="list-style-type: none"> Inform patients of risk of precipitated and protracted opioid withdrawal if opioids are used before taking naltrexone [c]. Emphasize the strong motivation and adherence needed for treatment success. Do not initiate naltrexone in patients with concomitant use of opioid analgesics or opioid agonists (e.g., methadone or BUP) with no plans for tapering or discontinuation. Contraindications: Concomitant use of opioid analgesics or opioid agonists (e.g., methadone or BUP), current physiologic opioid dependence, acute opioid withdrawal, and failure on the NLX challenge test or a positive urine screen for opioids. Warn patients of the increased risk of opioid overdose due to increased sensitivity after discontinuing naltrexone.
<p>Abbreviations: BUP, buprenorphine; NLX, naloxone; OUD, opioid use disorder; XR, extended-release.</p> <p>Notes:</p> <p>a. See full prescribing information for XR naltrexone (Vivitrol).</p> <p>b. For OUD treatment in pregnant individuals, see NYSDOH AI guideline Substance Use Disorder Treatment in Pregnant Adults.</p> <p>c. When withdrawal is precipitated abruptly by the administration of an opioid antagonist to an opioid-dependent patient, the resulting withdrawal syndrome can be severe. Symptoms of withdrawal usually appear within 5 minutes of ingestion of naltrexone and can last for up to 48 hours. Changes in mental status include confusion, somnolence, and visual hallucinations, and patients can experience significant fluid losses from vomiting and diarrhea requiring intravenous fluid administration.</p>		

Pain Management for Patients with OUD

Individuals with opioid use disorder (OUD) often have co-occurring pain, including acute and chronic pain. In general, patients who are taking buprenorphine or methadone for OUD treatment should continue to take their long-term treatment dose while optimizing nonopioid medications and nonpharmacologic treatments. Temporarily increasing the buprenorphine/naloxone or methadone dose or splitting the dosing frequency may be effective for managing acute pain; the addition of a short-acting full-agonist opioid can be considered for management of moderate to severe acute pain [ASAM 2020]. When adding a full-agonist opioid analgesic, patients will likely need a higher dose than opioid-naïve patients to achieve adequate analgesia [ASAM 2020].

Detailed recommendations for pain management for patients with OUD are beyond the scope of this guideline. Clinicians are advised to consult the [American Society of Addiction Medicine National Practice Guideline for the Treatment of Opioid Use Disorder: 2020 Focused Update > Special Populations: Individuals With Pain](#).

All Recommendations

☑ ALL RECOMMENDATIONS: TREATMENT OF OPIOID USE DISORDER

Overdose Prevention

- Clinicians should provide overdose prevention counseling (A3); prescribe, dispense, or offer resources for NLX (A2); and dispense or offer resources for fentanyl and xylazine test strips (if available) (A3) as part of OUD treatment evaluation [a].

Who to Treat

- Clinicians should offer pharmacologic treatment to adult patients with OUD (A1), including those who are not actively using opioids but are at risk of returning to use or overdose. (B3)
- Clinicians should *not* exclude patients from pharmacologic OUD treatment because of:
 - Previous OUD treatment failure, which is defined as the inability to adhere to medications for OUD or achieve treatment goals. (A3)
 - Lack of participation in structured psychosocial treatment, such as counseling, cognitive behavioral therapy, or contingency management [b]. (A1)
 - Co-occurring substance use or SUD. (A2)
- Before discharging a patient treated for an opioid-related overdose or complication, and as medically indicated, clinicians in an ED or other acute care setting should initiate or recommend pharmacologic OUD treatment. (A1)

Treatment Options

- Clinicians should obtain complete histories of patients' previous OUD treatment, including tolerance of and success with medication initiation, experience with long-term treatment, adherence challenges, adverse effects, treatment duration, and reasons for stopping treatment. (A2)
- BUP/NLX and methadone are the preferred treatments for OUD. Clinicians should inform patients with OUD about all available pharmacologic options (BUP, methadone, and XR naltrexone) and all formulations. (A3) See the guideline sections [Buprenorphine/Naloxone](#), [Methadone](#), and [Naltrexone](#).
- Because OUD is a chronic condition, clinicians should recommend long-term pharmacologic treatment rather than withdrawal management alone. (A1)
- In choosing the best option for OUD treatment, clinicians should engage patients in shared decision-making that accounts for the patient's opioid tolerance and preferences, available and accessible options, and comorbidities. (A3)

BUP/NLX: Preferred Treatment

- Clinicians should recommend coformulated BUP/NLX as a preferred treatment for individuals with OUD. (A1) See [Table 1: Considerations When Choosing Buprenorphine or Methadone \(Preferred Agents for Opioid Use Disorder Treatment\)](#).

BUP/NLX Initiation

- **Initiation setting:** Because both home-based (unobserved) initiation and office-based (observed) initiation are effective, clinicians should advise an initiation setting based on patients' experience, comfort, and preferences and clinicians' practice experience and support. (B2)
- **Precipitated withdrawal:** Clinicians should assess the potential for, educate patients about, and have a clear protocol for managing precipitated withdrawal. (A3)
- **Standard initiation:** To minimize the risk of precipitated withdrawal, clinicians should advise patients to wait for the onset of mild to moderate opioid withdrawal before starting BUP/NLX treatment. (A2)
 - As indicated, clinicians should provide adjunctive medications to relieve specific symptoms of acute opioid withdrawal (B2). See [Table 2: Adjunctive Medications to Relieve Acute Opioid Withdrawal Symptoms](#).
- **Low-dose BUP with opioid continuation (LDB-OC; previously known as microdosing or micro-induction):** For patients who may be unable to tolerate opioid withdrawal before starting BUP/NLX, or for patients who have had prior experience with precipitated withdrawal with standard initiation, clinicians should offer LDB-OC as an alternative initiation approach. (A2)

☑ ALL RECOMMENDATIONS: TREATMENT OF OPIOID USE DISORDER

BUP/NLX Dosing

- Clinicians should titrate BUP/NLX to the dose needed to control patients' cravings, reduce or prevent withdrawal symptoms, and support treatment goals. (A3) See [Table 3: Buprenorphine/Naloxone for Treatment of Opioid Use Disorder in Nonpregnant Adults](#).
- If a patient has continued symptoms of opioid withdrawal, cravings, or opioid use despite the maximum dose of BUP/NLX approved by the FDA (24 mg/6 mg daily), the clinician should pursue 1 or more of the following strategies:
 - Ensure the patient is taking the medication as prescribed [c]. (A3)
 - Increase the total daily dose of BUP up to 32 mg, particularly for patients with chronic fentanyl exposure, and reassess the need for higher (>24 mg daily) long-term dosing when patients have stabilized. (A2)
 - Offer adjunctive medication and psychosocial treatment to relieve specific symptoms that persist after acute opioid withdrawal, known as protracted withdrawal or post-acute withdrawal syndrome. (B3)
 - Offer long-acting injectable BUP. (A2)
 - Offer referral to methadone treatment if available and preferred by the patient. (A3)
- If a patient chooses to discontinue BUP/NLX treatment, the clinician should:
 - Discuss alternative medication, including methadone and naltrexone. (A1)
 - Inform the patient about the risks of recurrence of use, reduced tolerance, and opioid overdose. (A3)
 - Offer the patient a slow, tapering decrease schedule to minimize withdrawal symptoms. (B3)
- Clinicians should consult with or refer the patient to a clinician experienced in treatment of SUD if encountering challenges with BUP/NLX dosing (e.g., increases beyond the FDA-approved maximum dose), switching to long-acting injectable BUP, or tapering or discontinuing treatment. (A3)

Methadone: Preferred Treatment

- Clinicians should recommend methadone as a preferred treatment for individuals with OUD. (A1) See [Table 1: Considerations When Choosing Buprenorphine or Methadone \(Preferred Agents for Opioid Use Disorder Treatment\)](#).
- Methadone is available only through an OTP; therefore, the clinician should refer a patient for methadone treatment if methadone is preferred, if BUP/NLX is not available to the patient, or if the maximum dose of BUP/NLX does not control the patient's withdrawal symptoms or cravings. (A3)

Naltrexone: Alternative Treatment

- Clinicians should offer XR naltrexone to patients with OUD who prefer naltrexone treatment or who are not able to access or meet their treatment goals with methadone or BUP/NLX. (A3)
- When informing patients about XR naltrexone as a treatment option, clinicians should emphasize the strong motivation and adherence required for success. (B1)
- Before administering XR naltrexone, clinicians should administer an NLX (or low-dose naltrexone) challenge and confirm that patients do not react to ensure that opioids have been cleared from the system. (A2) See [Table 5: Extended-Release Naltrexone for Treatment of Opioid Use Disorder in Nonpregnant Adults](#).

Abbreviations: BUP, buprenorphine; ED, emergency department; FDA, U.S. Food and Drug Administration; NLX, naloxone; OTP, opioid treatment program; OUD, opioid use disorder; SUD, substance use disorder; XR, extended-release.

Notes:

- a. For full recommendations on overdose prevention, see NYSDOH AI guideline [Substance Use Harm Reduction in Medical Care > Implementing Substance Use Harm Reduction](#).
- b. If a patient is court-ordered to participate in psychosocial therapy, the clinician's primary responsibility is to maintain the therapeutic alliance and partner with the patient to address legal mandates.
- c. BUP/NLX should be dissolved under the tongue rather than swallowed.

Supplement: Guideline Development and Recommendation Ratings

Table S1: Guideline Development: New York State Department of Health AIDS Institute Clinical Guidelines Program

Developer	New York State Department of Health AIDS Institute (NYSDOH AI) Clinical Guidelines Program
Funding source	NYSDOH AI
Program manager	Clinical Guidelines Program, Johns Hopkins University School of Medicine, Division of Infectious Diseases. See Program Leadership and Staff .
Mission	To produce and disseminate evidence-based, state-of-the-art clinical practice guidelines that establish uniform standards of care for practitioners who provide prevention or treatment of HIV, viral hepatitis, other sexually transmitted infections, and substance use disorders for adults throughout New York State in the wide array of settings in which those services are delivered.
Expert committees	The NYSDOH AI Medical Director invites and appoints committees of clinical and public health experts from throughout New York State to ensure that the guidelines are practical, immediately applicable, and meet the needs of care providers and stakeholders in all major regions of New York State, all relevant clinical practice settings, key New York State agencies, and community service organizations.
Committee structure	<ul style="list-style-type: none"> • Leadership: AI-appointed chair, vice chair(s), chair emeritus, clinical specialist(s), JHU Guidelines Program Director, AI Medical Director, AI Clinical Consultant, AVAC community advisor • Contributing members • Guideline writing groups: Lead author, coauthors if applicable, and all committee leaders
Disclosure and management of conflicts of interest	<ul style="list-style-type: none"> • Annual disclosure of financial relationships with commercial entities for the 12 months prior and upcoming is required of all individuals who work with the guidelines program, and includes disclosure for partners or spouses and primary professional affiliation. • The NYSDOH AI assesses all reported financial relationships to determine the potential for undue influence on guideline recommendations and, when indicated, denies participation in the program or formulates a plan to manage potential conflicts. Disclosures are listed for each committee member.
Evidence collection and review	<ul style="list-style-type: none"> • Literature search and review strategy is defined by the guideline lead author based on the defined scope of a new guideline or update. • A comprehensive literature search and review is conducted for a new guideline or an extensive update using PubMed, other pertinent databases of peer-reviewed literature, and relevant conference abstracts to establish the evidence base for guideline recommendations. • A targeted search and review to identify recently published evidence is conducted for guidelines published within the previous 3 years. • Title, abstract, and article reviews are performed by the lead author. The JHU editorial team collates evidence and creates and maintains an evidence table for each guideline.
Recommendation development	<ul style="list-style-type: none"> • The lead author drafts recommendations to address the defined scope of the guideline based on available published data. • Writing group members review the draft recommendations and evidence and deliberate to revise, refine, and reach consensus on all recommendations. • When published data are not available, support for a recommendation may be based on the committee’s expert opinion. • The writing group assigns a 2-part rating to each recommendation to indicate the strength of the recommendation and quality of the supporting evidence. The group reviews the evidence, deliberates, and may revise recommendations when required to reach consensus.

Table S1: Guideline Development: New York State Department of Health AIDS Institute Clinical Guidelines Program

Review and approval process	<ul style="list-style-type: none"> Following writing group approval, draft guidelines are reviewed by all contributors, program liaisons, and a volunteer reviewer from the AI Community Advisory Committee. Recommendations must be approved by two-thirds of the full committee. If necessary to achieve consensus, the full committee is invited to deliberate, review the evidence, and revise recommendations. Final approval by the committee chair and the NYSDOH AI Medical Director is required for publication.
External reviews	<ul style="list-style-type: none"> External review of each guideline is invited at the developer’s discretion. External reviewers recognized for their experience and expertise review guidelines for accuracy, balance, clarity, and practicality and provide feedback.
Update process	<ul style="list-style-type: none"> JHU editorial staff ensure that each guideline is reviewed and determined to be current upon the 3-year anniversary of publication; guidelines that provide clinical recommendations in rapidly changing areas of practice may be reviewed annually. Published literature is surveilled to identify new evidence that may prompt changes to existing recommendations or development of new recommendations. If changes in the standard of care, newly published studies, new drug approval, new drug-related warning, or a public health emergency indicate the need for immediate change to published guidelines, committee leadership will make recommendations and immediate updates and will invite full committee review as indicated.

Table S2: Recommendation Ratings and Definitions

Strength	Quality of Evidence	
A: Strong B: Moderate C: Optional	1	Based on published results of at least 1 randomized clinical trial with clinical outcomes or validated laboratory endpoints.
	*	Based on either a self-evident conclusion; conclusive, published, in vitro data; or well-established practice that cannot be tested because ethics would preclude a clinical trial.
	2	Based on published results of at least 1 well-designed, nonrandomized clinical trial or observational cohort study with long-term clinical outcomes.
	2†	Extrapolated from published results of well-designed studies (including nonrandomized clinical trials) conducted in populations other than those specifically addressed by a recommendation. The source(s) of the extrapolated evidence and the rationale for the extrapolation are provided in the guideline text. One example would be results of studies conducted predominantly in a subpopulation (e.g., one gender) that the committee determines to be generalizable to the population under consideration in the guideline.
	3	Based on committee expert opinion, with rationale provided in the guideline text.
